# Which traits are important for a species to determine phenology?

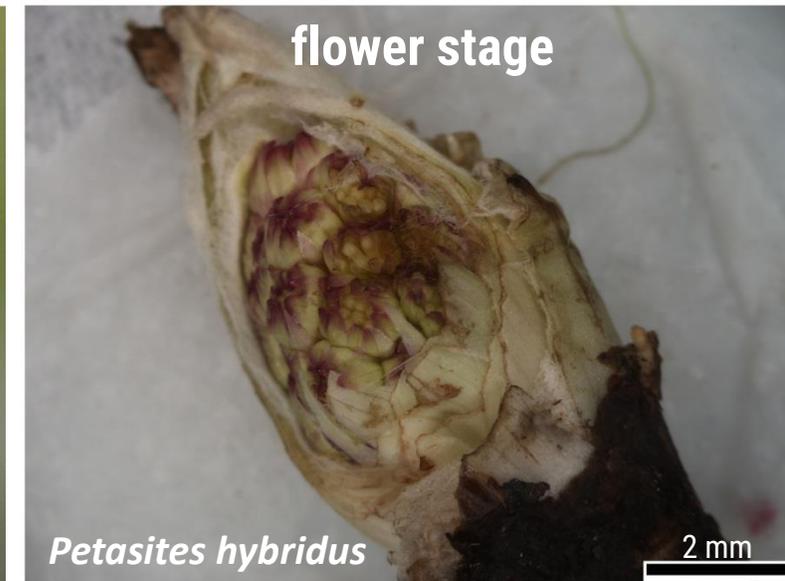

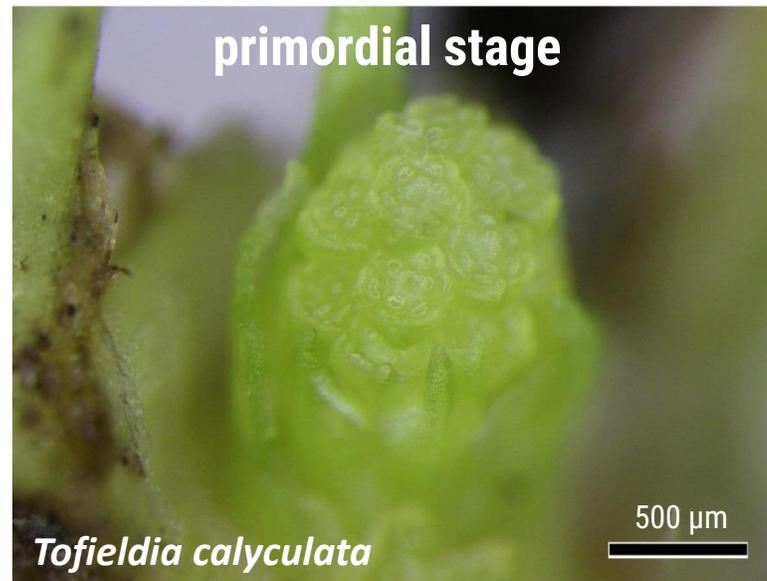

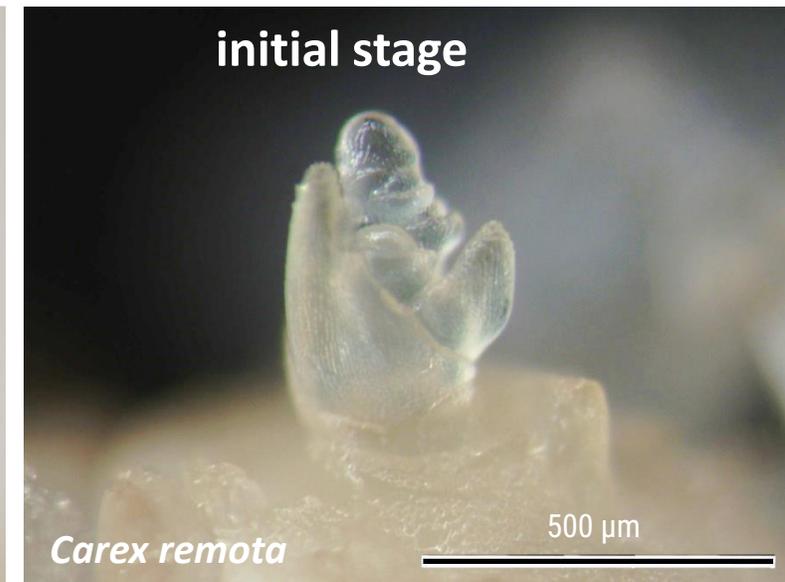

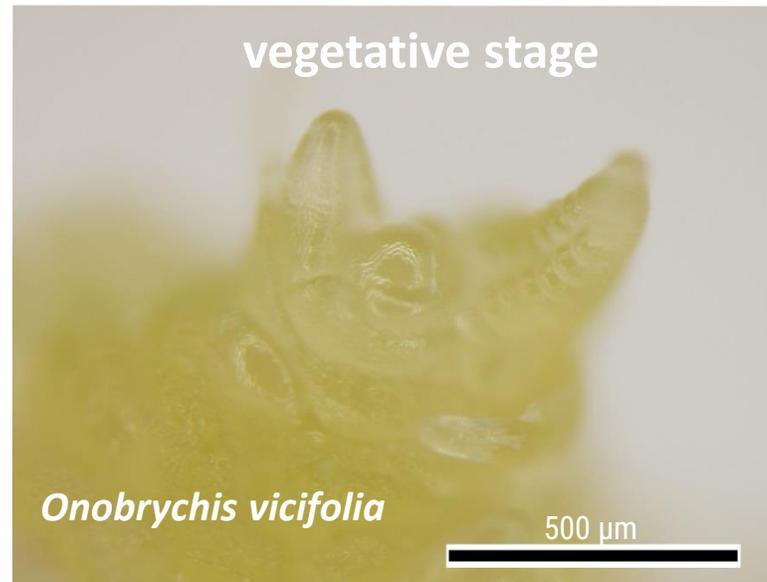

$N_{area}$  is most influential on the shift in phenology

Functional traits are more important to explain shifts in phenology than abiotic factors

**inflorescence preformation in buds** clasified:

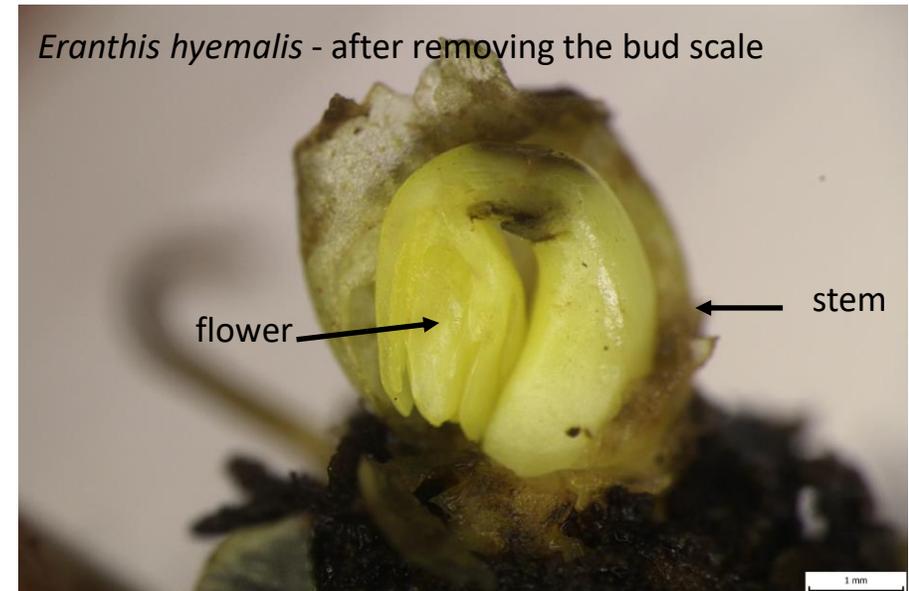

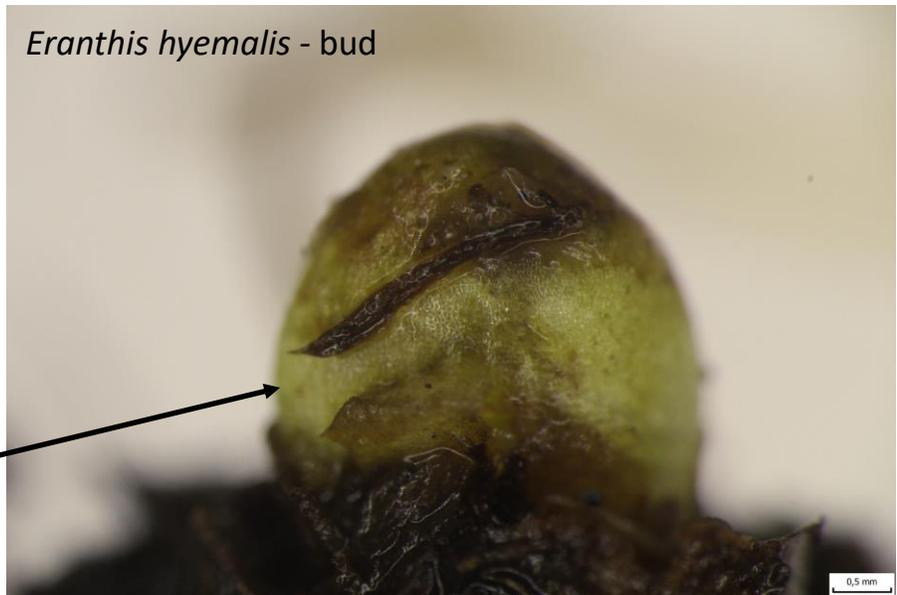

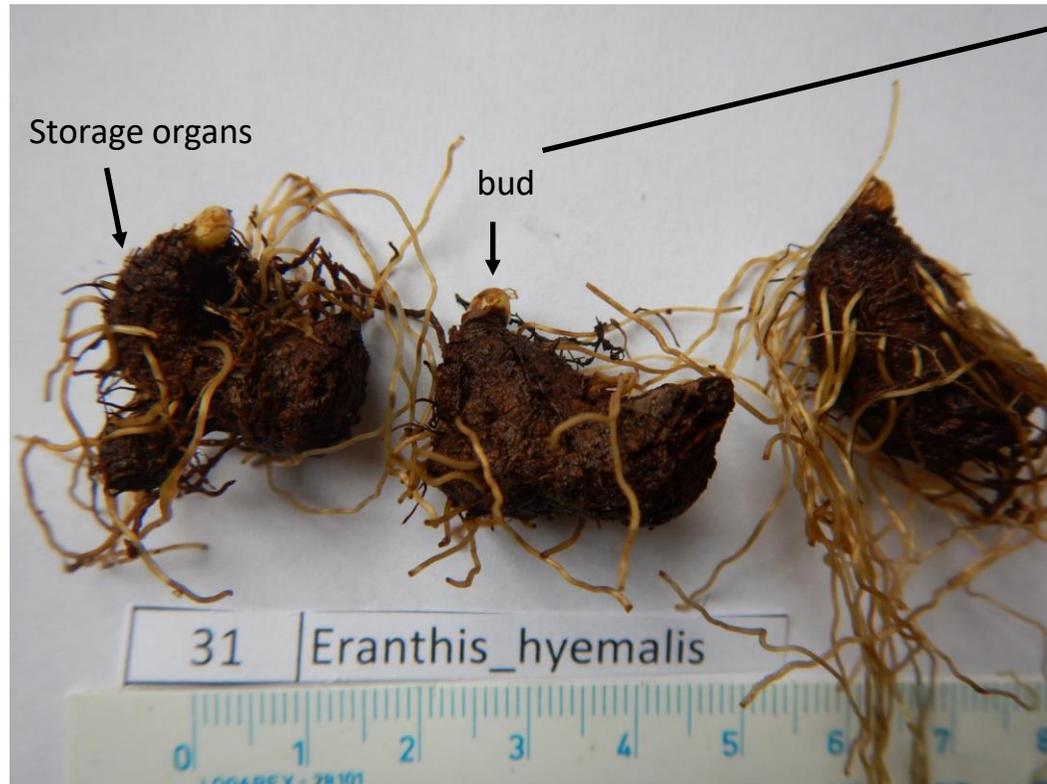

- 0 - only vegetative meristem
- 1 - initial stage – the meristem undergoes the transition to generative stage
- 2 - primordial – the first primordia of few flower organs are visible
- 3 - primordial advanced – more primordia visible
- 4 - full primordial – all primordia of the flower organs are present
- 5 - flower stage – all inflorescences developed

Schnablová et al., 2020, New Phytologist

# Inflorescence preformation

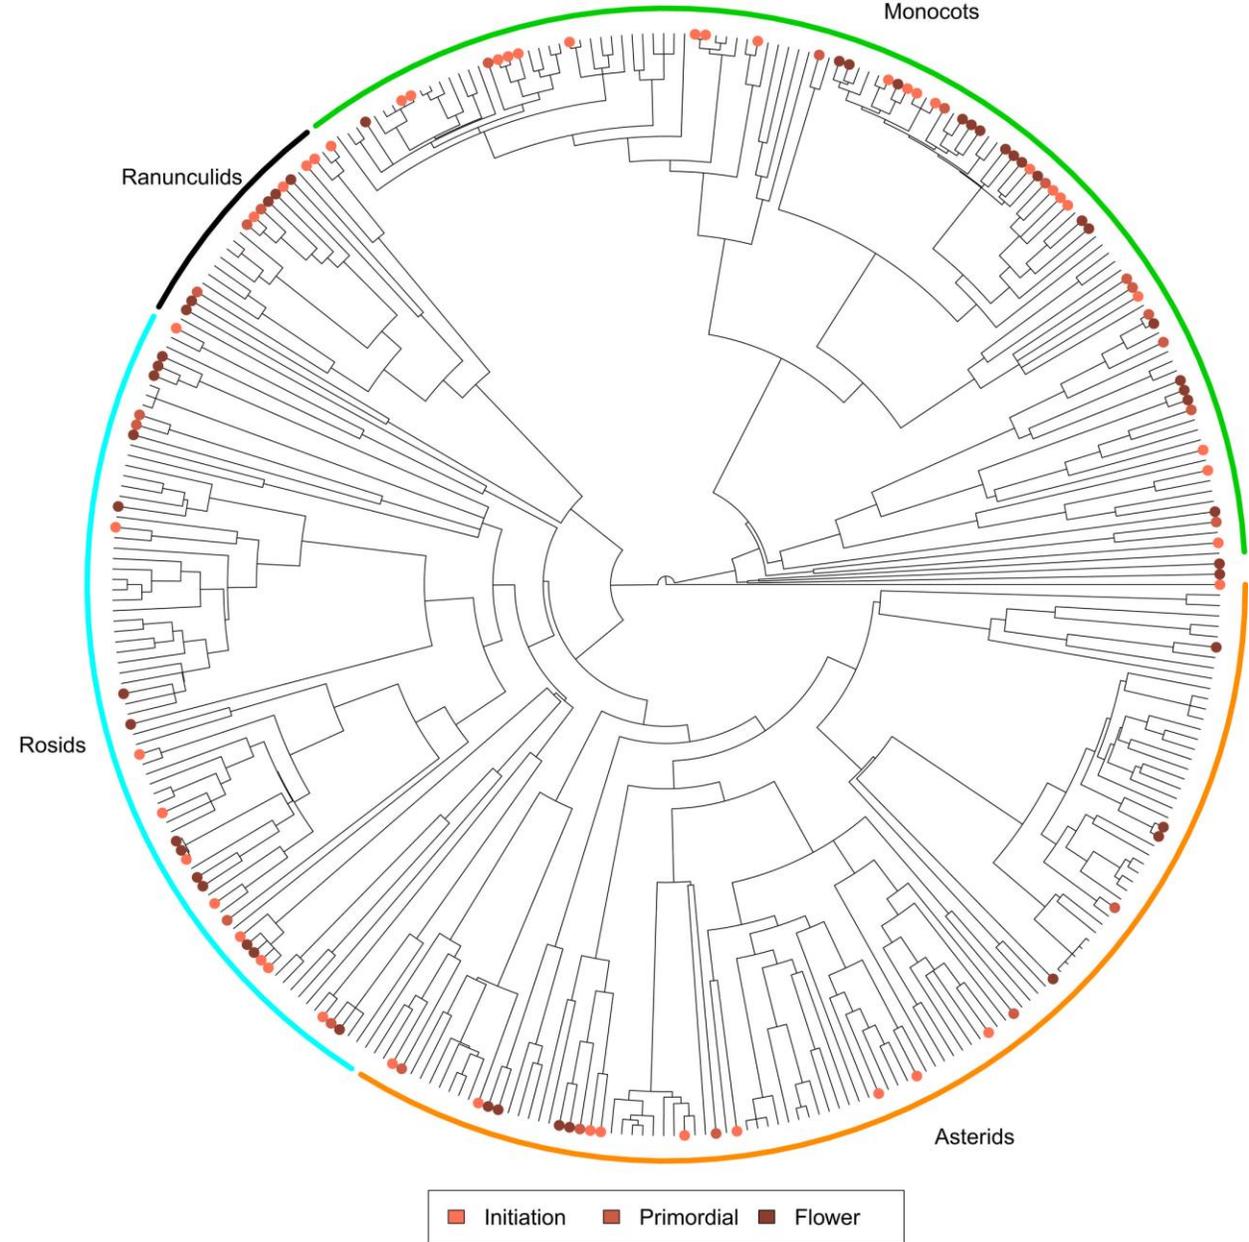

➔ Preparation of bud preformation

# Preformation buds

➔ Widely distributed, but non-randomly between species (phylogenetic signal)

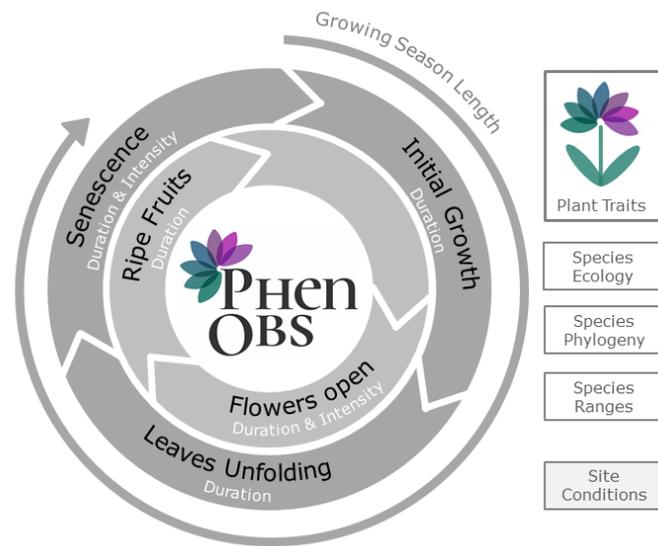

➔ Is this important for phenology?

Schnablová et al., 2020, New Phytologist

# The Phenobs initiative – monitoring phenology in herbaceous species

Network of 20 botanical gardens on the northern hemisphere

➔ Bud collection for 86 species

➔ Buds collected in Jena and Průhonice

### Locations

Overview of botanical gardens in their bioclimatic zone.

- boreal, subcontinental
- boreal, xeric
- boreal, oceanic
- temperat, hyperoceanic
- temperat, continental
- temperat, oceanic
- mediterranean, oceanic
- submediterranean

Nordt et al. (2021), Journal of Functional Ecology

# Bud collection in Jena 26.11.2020

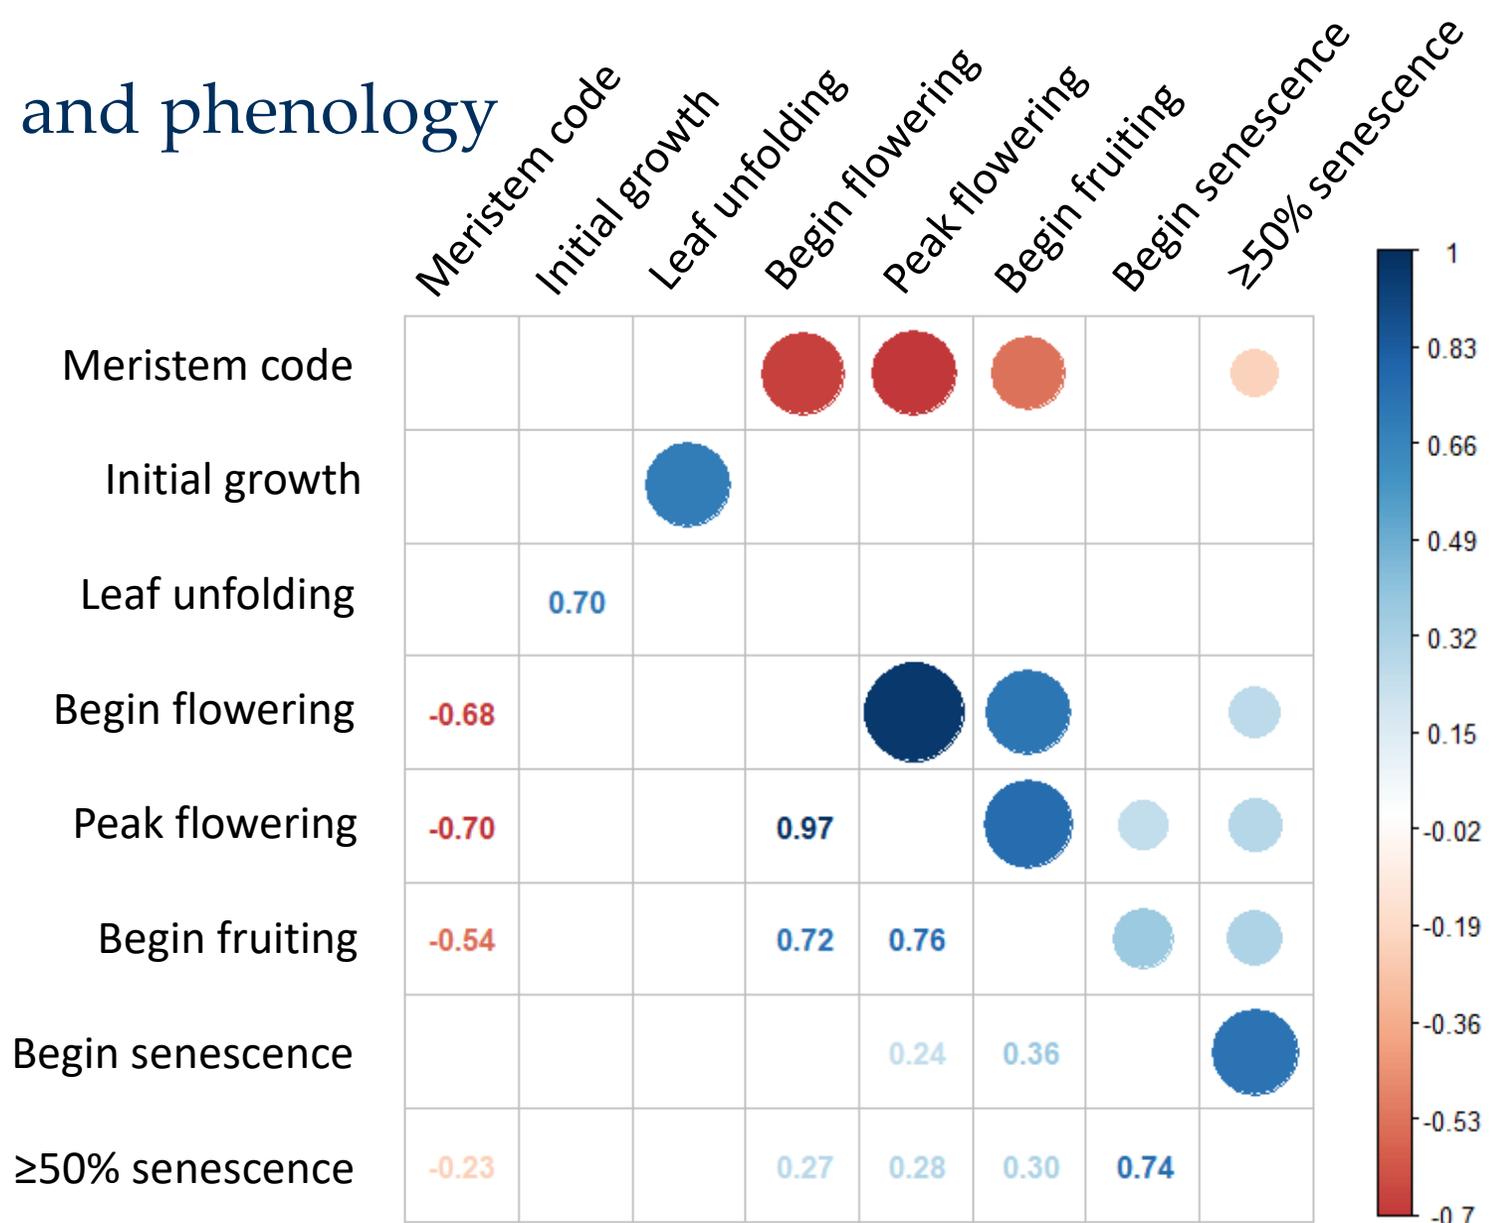

Ranunculaceae  
**Eranthis  
hyemalis**  
(L.) Solms.  
S- u. SO-Europa, W-Asien  
Winterling

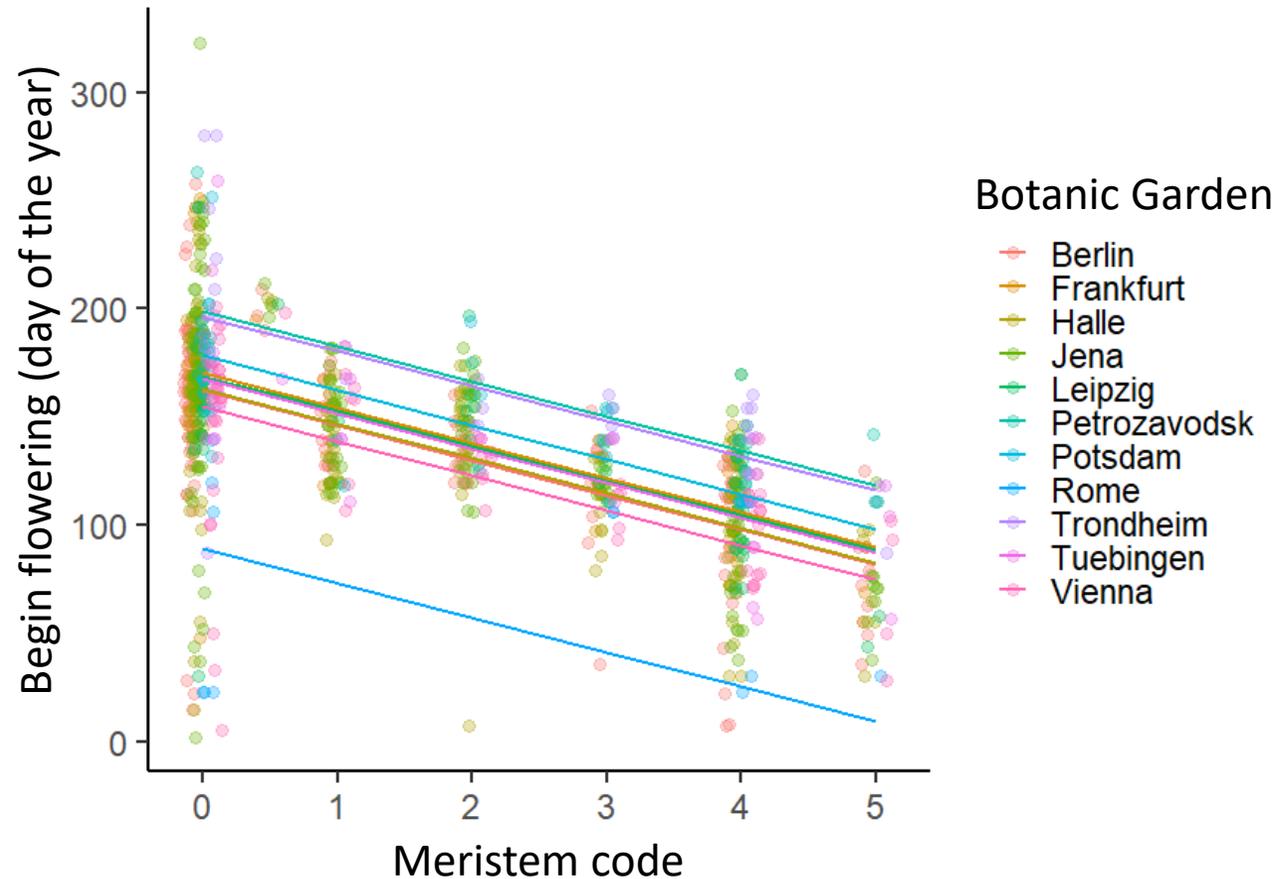

# Inflorescence preformation and phenology

- ➔ Plants with highly developed meristems grow and flower earlier and have an earlier fruit set and start senescence earlier
- ➔ Meristem development has no effect on initial growth and begin of senescence

# Phenology between the gardens

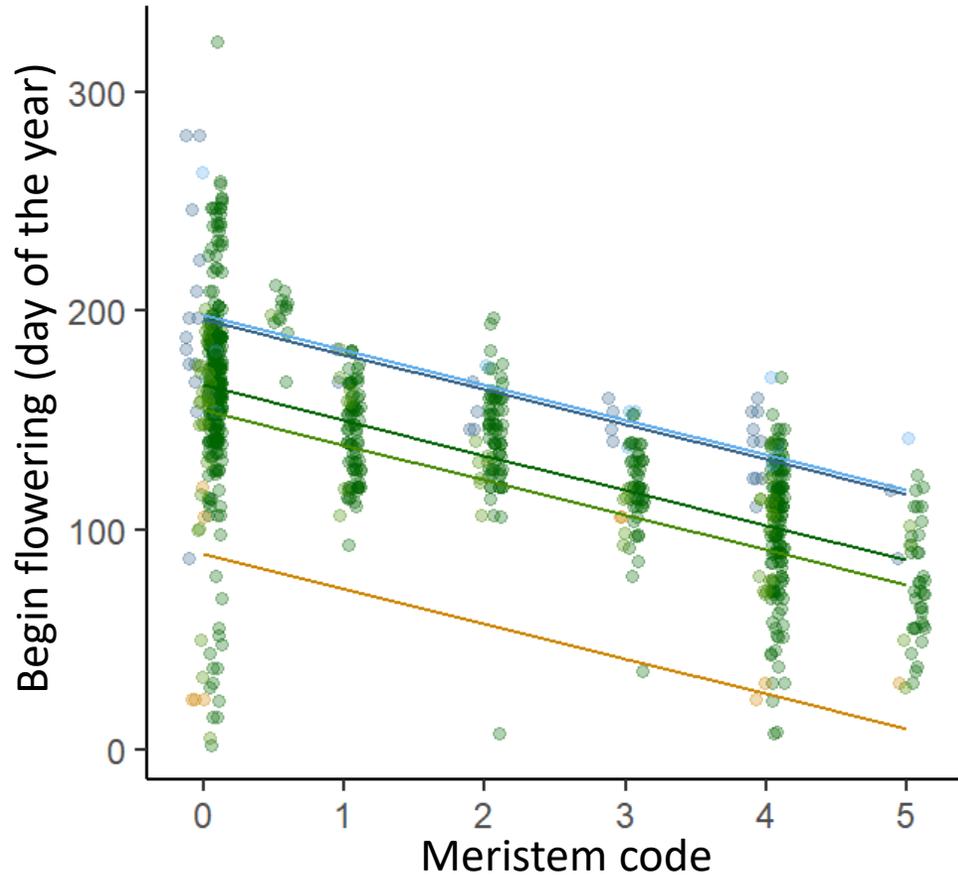

The higher meristem developed, the earlier the beginning of flowering

Trend consistent between gardens

# Phenology between the gardens

$R^2 = 0.44$ ,  $F_{5, 806} = 126.9$ ,  $p < 0.001$

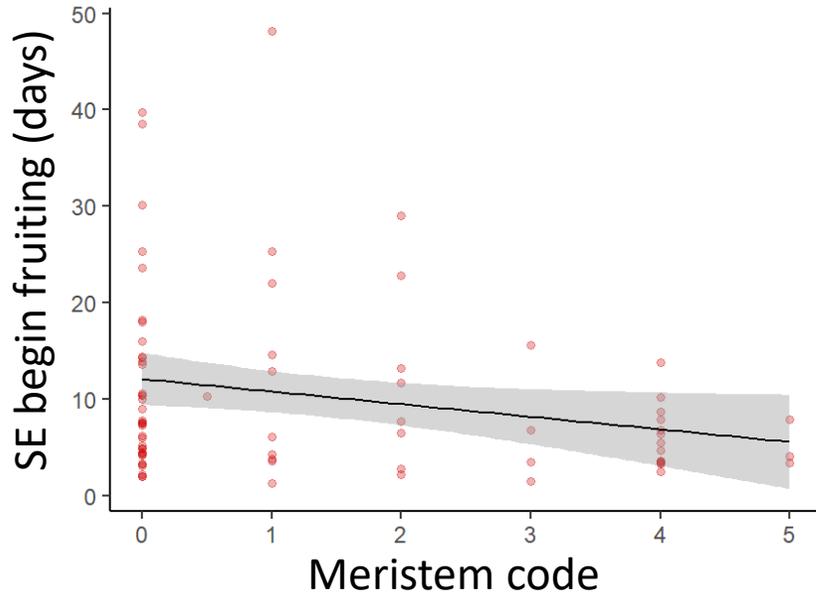

- boreal, subcontinental
- boreal, xeric
- boreal, oceanic
- temperat, hyperoceanic
- temperat, continental
- temperat, oceanic
- mediterranean, oceanic
- submediterranean

Also consistent across climate types of gardens

# Meristem code and changes in phenology

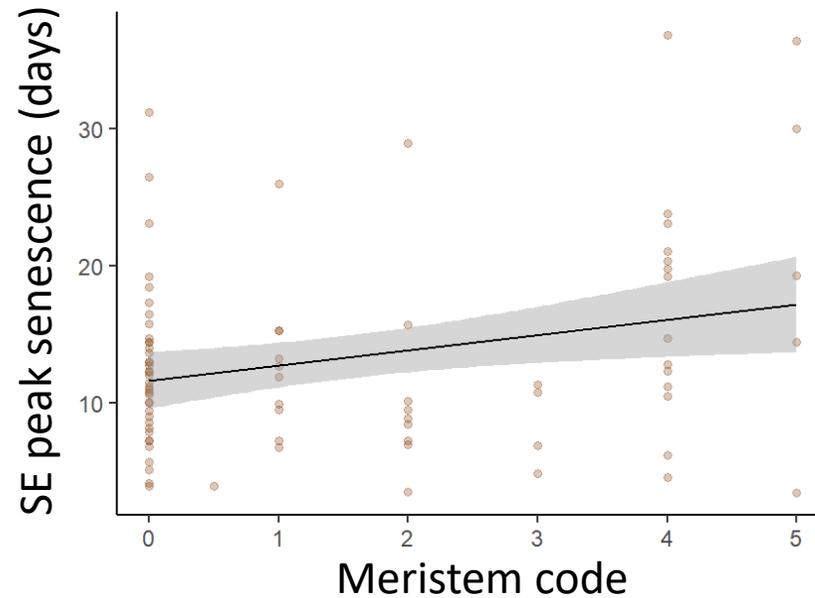

Variability in phenology assessed via the standard error

$R^2 = 0.06$ ,  $F_{1,75} = 4.5$ ,  $p < 0.05$

The higher meristem is developed, the less variable the onset of fruiting

$R^2 = 0.07$ ,  $F_{1,80} = 6.2$ ,  $p < 0.05$

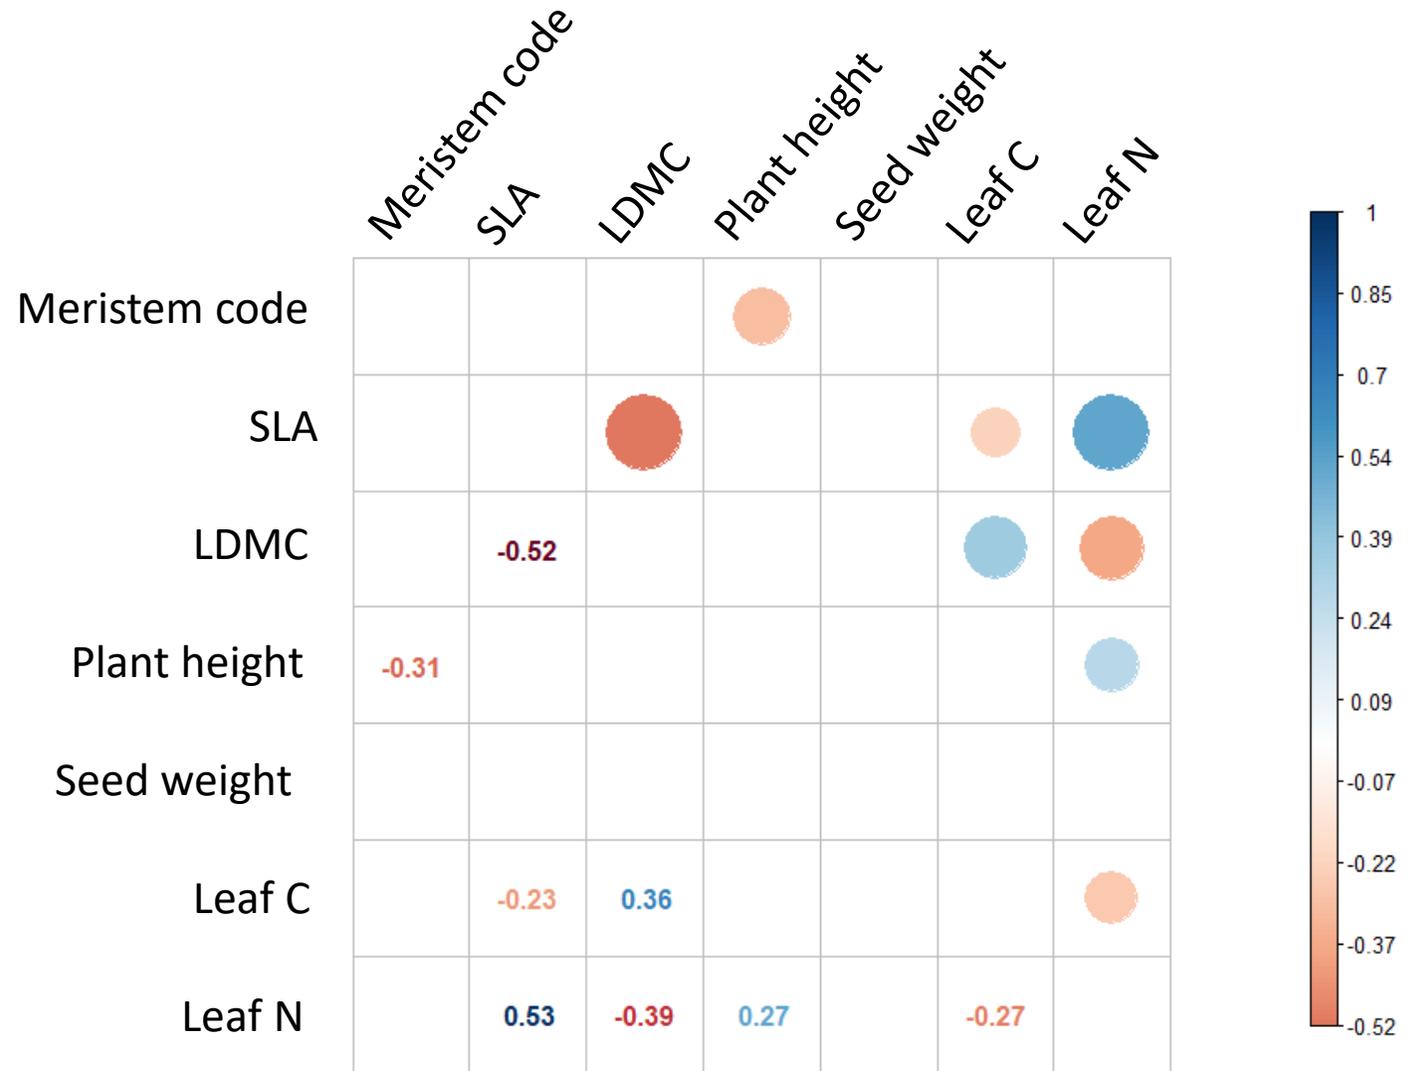

... but the more variable the onset of senescence

# Meristem code and traits

➔ Smaller plants tend to have higher developed meristems

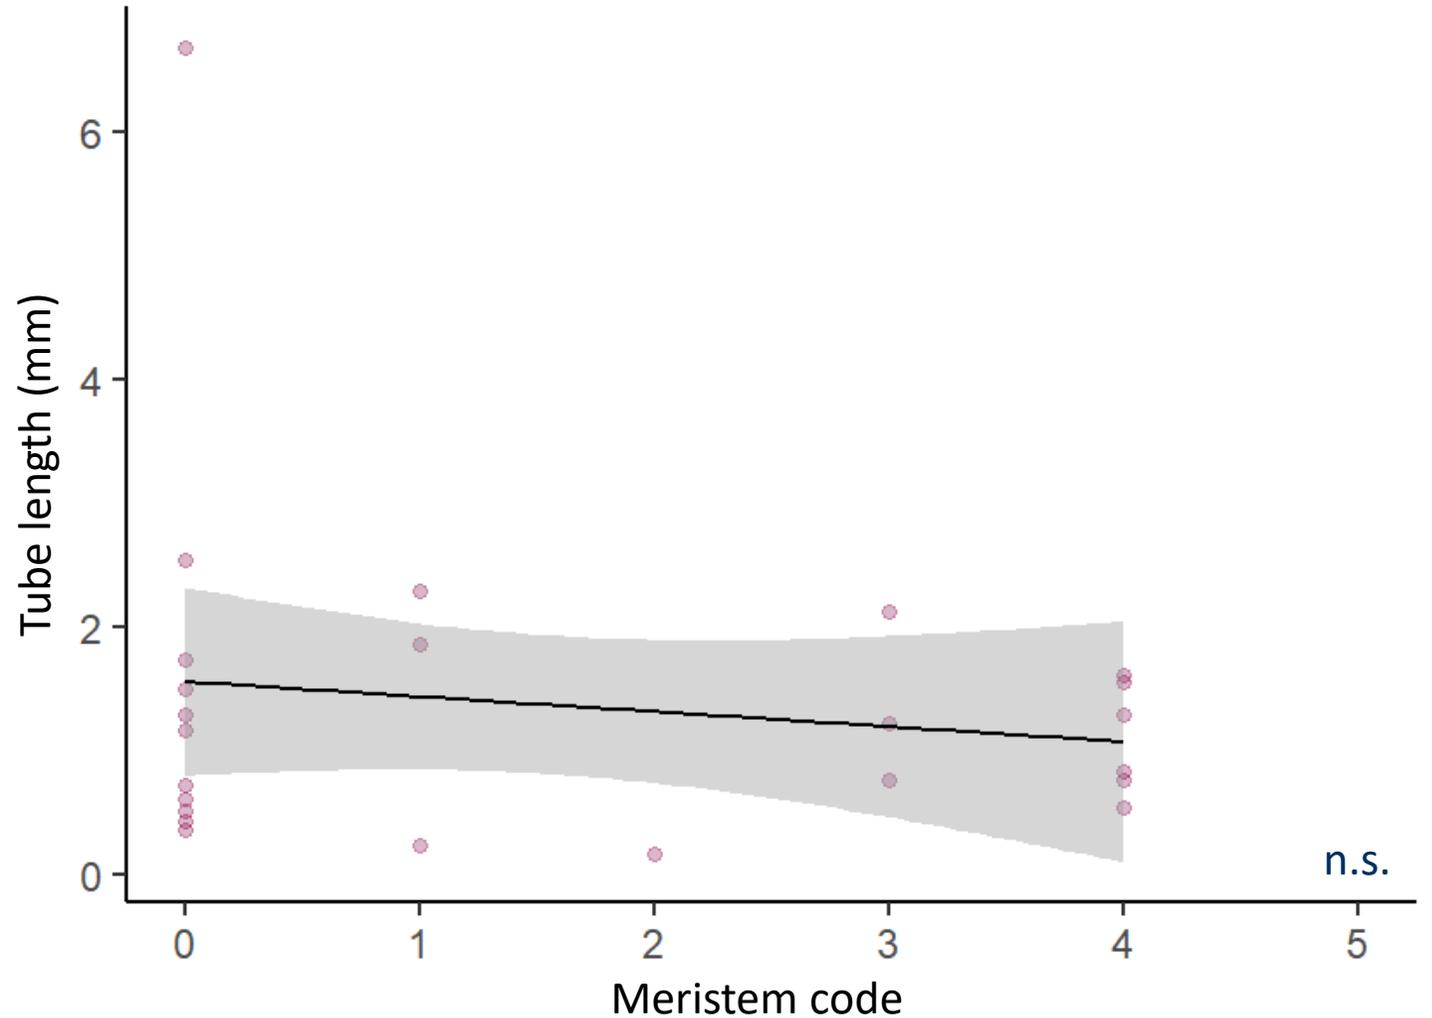

➔ No relationship with other leaf traits or seedmass

# Meristem code and flowers

Meristem preformation is not related to flower traits such as tube length, nectar content or flower size

# Take home message

1. Inflorescence preformation is a widely understudied plant trait which affects phenology of species
2. The higher the stage of preformation, the earlier flowering phenology
3. Preformation impacts the variability of fruiting and senescence within species
4. Preformation is not linked to leaf or flower traits besides plant height

# Thank you for listening
