

LAND SURFACE PHENOLOGY AS INDICATOR OF GLOBAL TERRESTRIAL ECOSYSTEM DYNAMICS

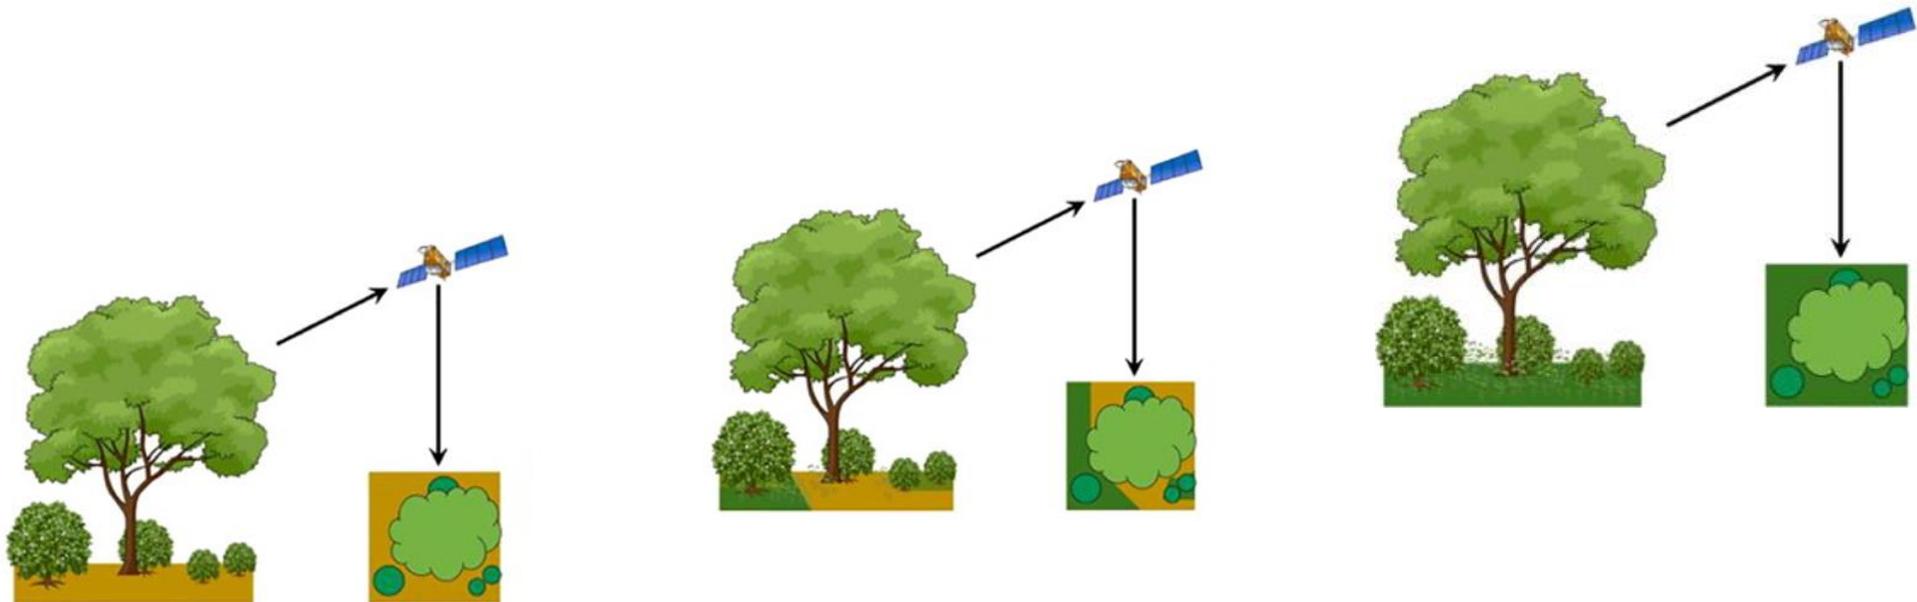

VICTOR RODRIGUEZ-GALIANO

DEPARTMENT OF PHYSICAL GEOGRAPHY AND REGIONAL GEOGRAPHIC ANALYSIS

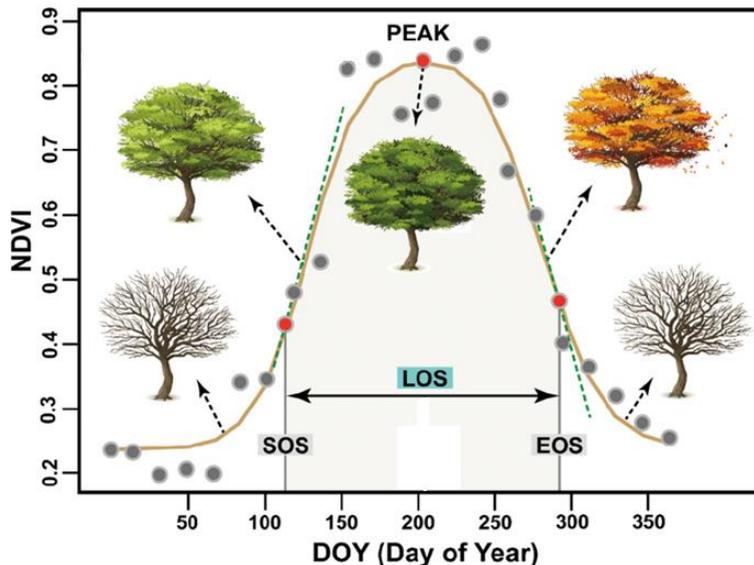

UNIVERSITY OF SEVILLE

LAND SURFACE PHENOLOGY BASICS

- **Land surface phenology (LSP)** is defined as the study of the seasonal dynamics of the vegetated land surface observed from remotely sensed satellite imagery. LSP is estimated from **vegetation indices (VI)** or **biophysical variables (BV)** time-series, which can be used as proxy for vegetative vigour and amount.
- VI (or BV) can be used to obtain specific phenological metrics or **phenometrics**. These phenometrics are ecologically-meaningful metrics that may be considered as proxies of timing of spring and autumn phenophases. Phenometrics include the **start of the (growing) season (SOS)**, also referred in the literature as the green-up date (GUD), onset of greenness (OG) or spring phenology; the **end of the (growing) season (EOS)**, also called end of senescence (EOS), end of greenness, dormancy or autumn phenology; and the **length of the (growing) season (LOS)**.

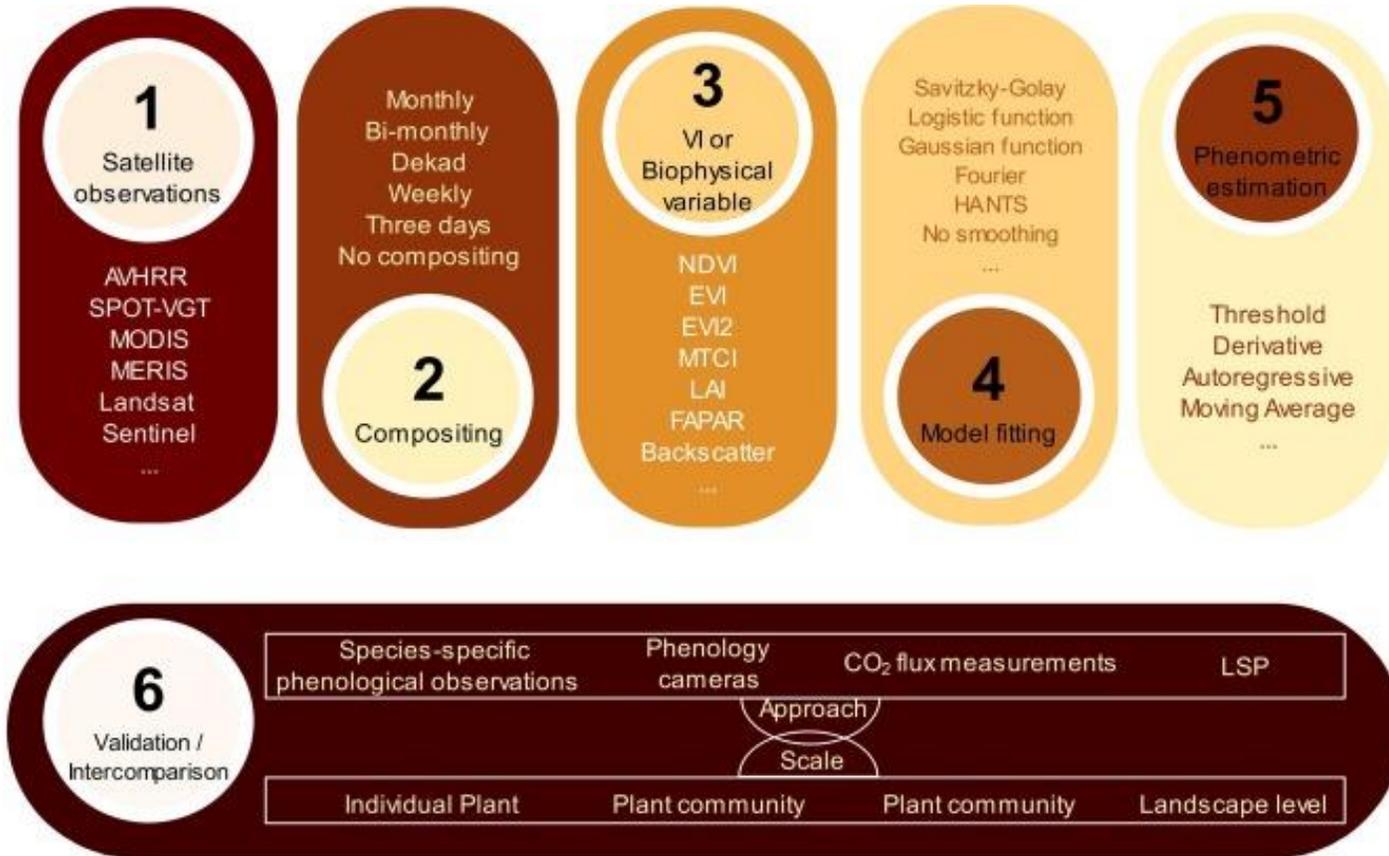

Phenometrics extracted from VI time series datasets.

SOS: the point in time extracted from the ascending phase (pre-maximum phase) of the curve of the VI (or BV), which could be associated to timing of spring phenophases (e. g., **leaf unfolding** or **flowering**).

EOS: the point in time extracted from the descending phase (post-maximum phase) of the curve of the VI (or BV variable), which could be related to timing of autumn phenophases (e. g., **autumnal colouring of leaves** or **leaf fall**)

LOS: difference between SOS and EOS, which could be associated to the complete temporal extension of the period of vegetative development of plants.

Schematic diagram on the steps involved in LSP estimation from satellite data. Extracted from Caparros-Santiago et al. (2021).

Review Article

Land surface phenology as indicator of global terrestrial ecosystem dynamics: A systematic review

Jose A. Caparros-Santiago^a, Victor Rodriguez-Galiano^{a,*}, Jadunandan Dash^b

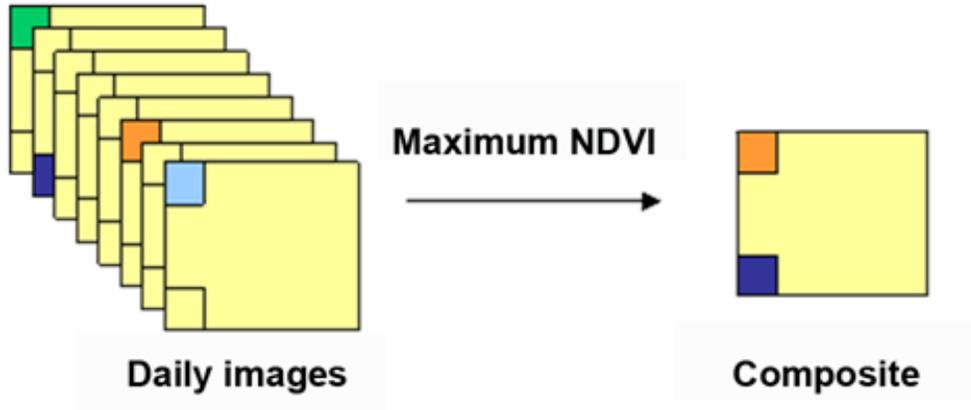

^a Departamento de Geografía Física y Análisis Geográfico Regional, Universidad de Sevilla, Seville 41004, Spain
^b School of Geography and Environmental Science, University of Southampton, Southampton SO17 1BJ, United Kingdom

1. SATELLITE OBSERVATIONS

Summary of some common satellite sensors.

SENSORS	SPATIAL RESOLUTION	TEMPORAL RESOLUTION
AVHRR (NOAA)	1.1 km	Daily
MODIS (Terra and Aqua)	250 m (bands 1-2) 500 m (bands 3-7) 1000 m (bands 8-36)	1-2 days
SPOT-VGT	1.1 km	Daily
VIIRS	375 m (Bands I) and 750 m (Bands M)	Daily
IRS-WiFS	180 m	5 days
Landsat 4-5 TM	30 m (VIS-NIR); 120 m (TIR)	16 days
Landsat 7 ETM+	30 m (VIS-NIR); 60 m (TIR); 15 m (panchromatic band)	16 days
Landsat 8 OLI	30 m (VIS-NIR-TIR); 15 m (panchromatic band)	16 days
Sentinel 2 A/B MSI	10 m (bands 2 (B),3 (G),4 (R),8 (NIR), 20 m (bands 5, 6, 7, 8 A, 11, 12); 60 m (bands 1, 9, 10)	5 days
GeoEye-1	0.41 m panchromatic and 1.65 m 4-band multi-spectral data	1-4 days

2. COMPOSITING

- Satellite **composites** instead of daily or near-daily images allows to reduce the amount of data, optimising the computational cost, and minimising atmospheric effects (e. g., cloud cover).
- ❖ **Composite:** statistical aggregated value (e. g., maximum, median or mean value) at pixel level within a fixed temporal window.

Example of the temporal window of image composites of some satellite products

SATELLITE	SENSOR	TEMPORAL RESOLUTION	SATELLITE PRODUCT	TEMPORAL WINDOW OF COMPOSITE
NOAA	AVHRR (1981-current)	Daily	PAL AVHRR	10 days
			GIMMS AVHRR	15 days
Terra / Aqua	MODIS (1999-current)	1-2 days	MOD09A1	8 days
			MOD09Q1	8 days
			MOD13Q1	16 days
S-NPP	VIIRS (2011-current)	Daily	VNP09H1	8 days
			VNP13A1	16 days

II. LAND SURFACE PHENOLOGY ESTIMATION

3. VEGETATION INDICES AND BIOPHYSICAL VARIABLES

Summary of common satellite-derived remote sensing VI. Adapted from Zeng et al. (2020)

VI	CALCULATION	CHARACTERISTICS
NDVI (Normalised Difference Vegetation Index)	$\frac{\rho_{\text{NIR}} - \rho_{\text{RED}}}{\rho_{\text{NIR}} + \rho_{\text{RED}}}$	Sensitive to chlorophyll, but saturated in areas with high biomass density. It minimises some types of noise (e. g., cloud shadows, topographic effects etc.)
EVI (Enhanced Vegetation Index)	$G \times \frac{\rho_{\text{NIR}} - \rho_{\text{RED}}}{\rho_{\text{NIR}} + (C_1 \times \rho_{\text{RED}} - C_2 \times \rho_{\text{BLUE}}) + L}$	Introducing atmosphere-sensitive blue band to correct the red band for aerosol influences. Sensitivity in areas with high biomass density.
EVI2 (A two-band Enhanced Vegetation Index)	$G \times \frac{\rho_{\text{NIR}} - \rho_{\text{RED}}}{\rho_{\text{NIR}} + C \times \rho_{\text{RED}} + L}$	Similar to EVI, retaining the soil-noise adjustment function and maintaining the improved sensitivity and linearity in high biomass regions, with the absence of a blue band.
MTCI (MERIS Terrestrial Chlorophyll Index)	$\frac{\rho_{753.75} - \rho_{708.75}}{\rho_{708.75} - \rho_{681.25}}$	Sensitive to high chlorophyll content and limited sensitive to atmospheric effect or spatial resolution.
OTCI (Sentinel-3 OLCI Terrestrial Chlorophyll Index)		
NDWI (Normalised Difference Water Index)	$\frac{\rho_{\text{NIR}} - \rho_{\text{SWIR}}}{\rho_{\text{NIR}} + \rho_{\text{SWIR}}}$	Sensitive to the water
PPI (Plant Phenology Index)	$-K \times \ln \frac{(M - \text{DVI})}{(M - \text{DVI}_S)}$	It minimize the snow influence and increase the sensitivity to minor seasonal variation in dense canopy greenness of the boreal forests

2

Summary of common satellite-derived remote sensing BV. Adapted from Zeng et al. (2020) and Caparros-Santiago et al. (2021)

BV	Characteristics
LAI (Leaf Area Index)	Biophysical variable that measures the leaf area (m ²) per unit of ground surface area (m ²).
FAPAR (Fraction of Absorbed Photosynthetically Active Radiation)	Biophysical variable that measures the amount of solar radiation absorbed by the canopy during photosynthetic activity.
SIF (solar-induced chlorophyll fluorescence)	Biophysical variable that quantifies a small portion of solar energy absorbed by plants (1-2%), which is not used for photosynthesis and is therefore re-emitted at a longer wavelength.
AGB (Above-ground biomass)	Biophysical variable that is determined by the vegetation cover and its height.

4. MODEL FITTING

--- Raw NDVI — Savitzky-Golay — Asymmetric Gaussian Function — Double Logistic Function — Discrete Fourier Transform

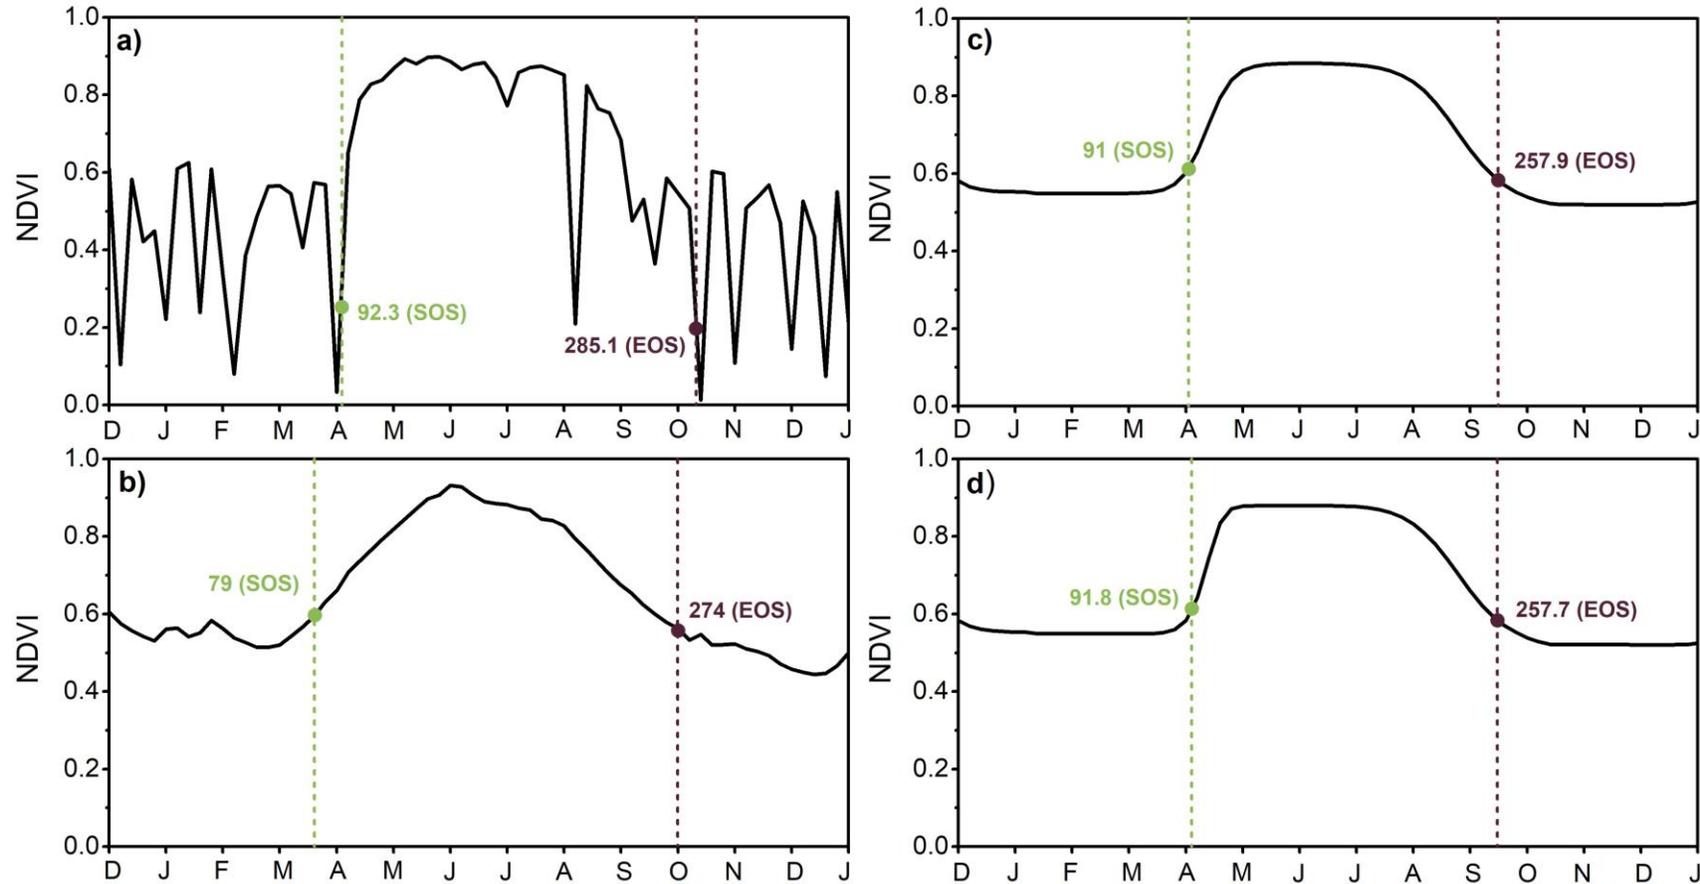

Evergreen needleleaf forests
(41° 59' 33.086" N; 02° 47' 43.125" W)

Deciduous broadleaf forests
(42° 22' 13.207" N; 02° 55' 8.891" W)

Grasslands
(42° 34' 50.023" N; 05° 09' 48.131" W)

Raw and smoothed MODIS-NDVI time series for different land covers. Adapted from Caparros-Santiago et al., (2021).

5. PHENOMETRIC EXTRACTION

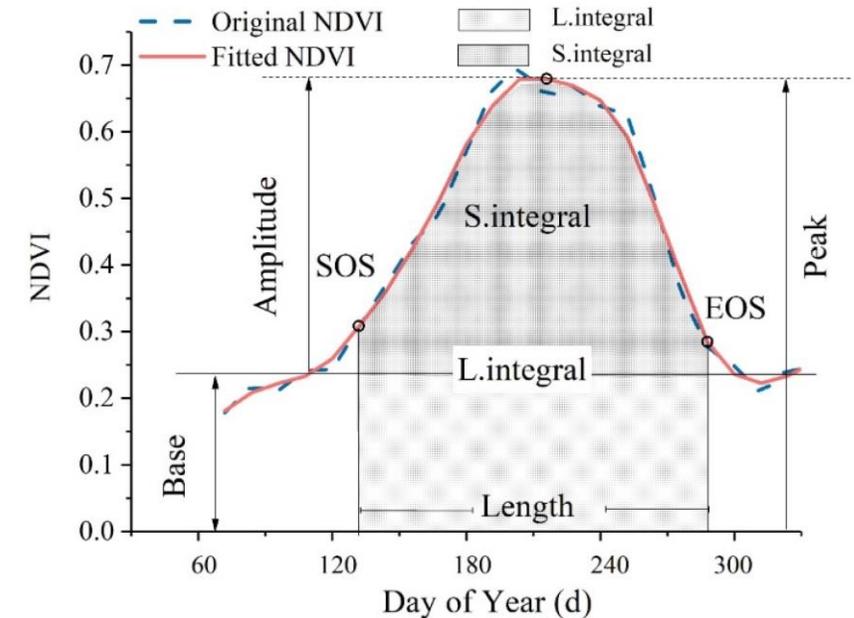

Phenometrics derived from **a) raw NDVI**; **b) smoothed NDVI** using a **Savitzky-Golay** filter; **c) smoothed NDVI** using a **double logistic function**; and **d) smoothed NDVI** using an **asymmetric Gaussian function**. A **20% threshold-based method** was used to extract SOS and EOS. These phenometrics are expressed in Julian days. The selected pixel is representative of a deciduous broadleaf forest (42° 22' 13.207" N; 02° 55'8.891" W). Adapted from Caparros-Santiago et al., (2021).

5. PHENOMETRIC EXTRACTION

THRESHOLD-BASED TECHNIQUE

SOS is defined as the date (e. g., day of the year; DOY) on which the pre-processed VI reaches a specific upward threshold before maximum, whilst the **EOS** date is defined as the point at which the adjusted curve crosses a specific downward threshold after maximum. These thresholds can be:

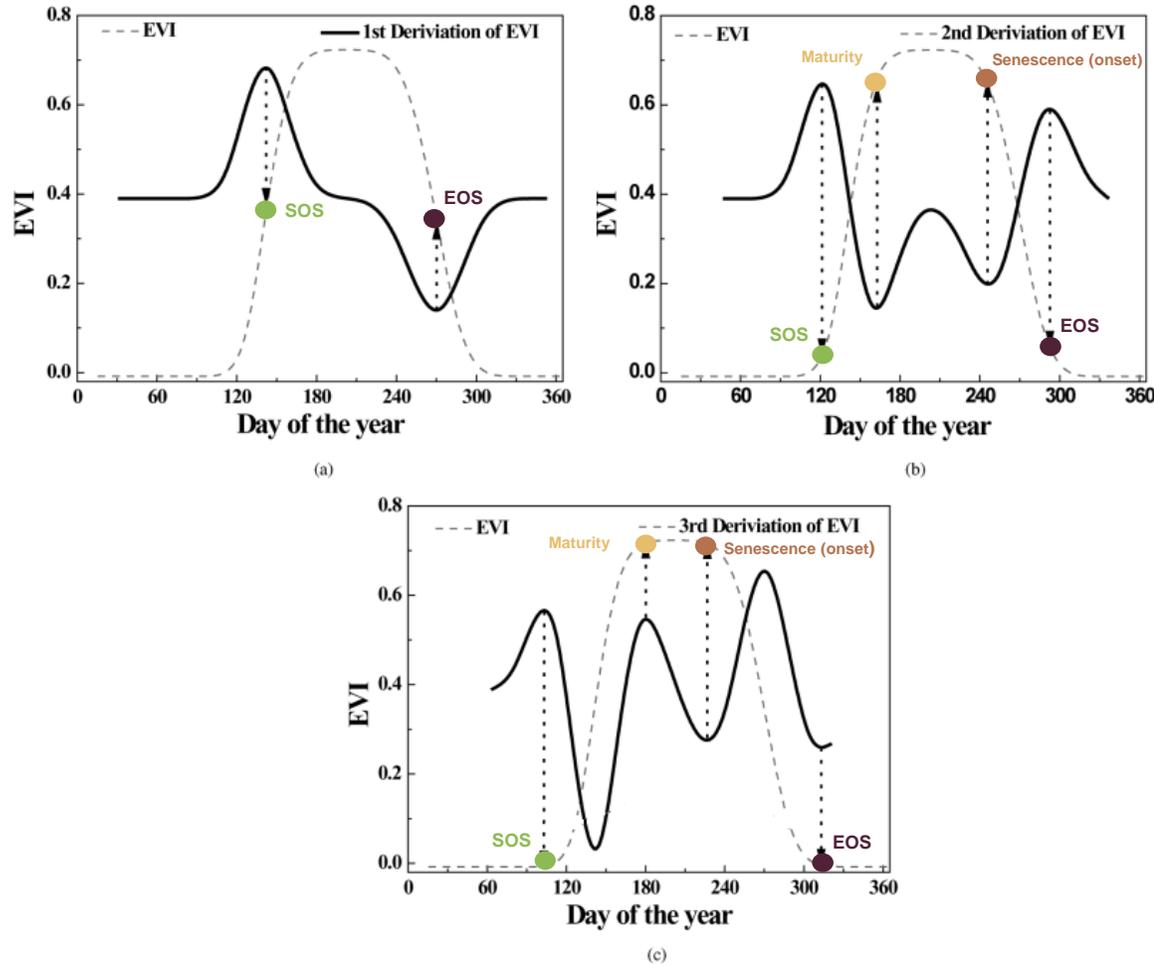

- **Relative thresholds:** **SOS** and **EOS** are defined as the moment when the smoothed VI trajectory reaches a percentage of the amplitude between a specific minimum level (e. g., base level; given as the average of the left and right minimum values) and the maximum value (Jönsson and Eklundh, 2002).
- **Absolute thresholds:** **SOS** and **EOS** are defined as the timing when the smoothed VI curve reached a specific absolute VI value (e. g., $SOS = 0.52$, $EOS = 0.56$) (Du et al., 2014)).
- **Thresholds based on VI ratio:** **SOS** and **EOS** are defined as the time when the smoothed VI curve reached a VI ratio. This threshold is based on a relationship between maximum and minimum VI values (Piao et al., 2006).

Example of the extraction of phenometrics from a **relative threshold-based technique**. **SOS** was defined as the timing (DOY) when the smoothed NDVI curve reached the 25% of its amplitude in upward direction before maximum, while the **EOS** was defined as the date (DOY) at which the smoothed NDVI curve fell to 25% of the amplitude after maximum. Extracted from Ma et al. (2020).

Ma, J., Zhang, C., Guo, H., Chen, W., Yun, W., Gao, L., & Wang, H. (2020). Analyzing ecological vulnerability and vegetation phenology response using NDVI time series data and the BFAST algorithm. *Remote Sensing*, 12, 1-21

5. PHENOMETRIC EXTRACTION

DERIVATIVE-BASED TECHNIQUES

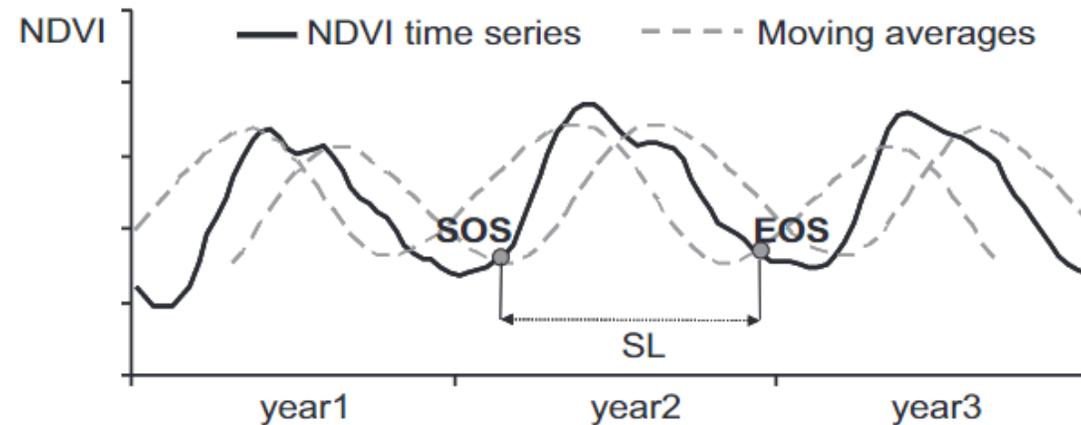

- The local maximum and minimum of the **FIRST DERIVATIVE** curve corresponds to the maximum rate of increase and decrease of the corresponding **greenup (SOS)** and **brown-down (EOS)** processes.
- The local maximums of the **SECOND DERIVATIVE** curve correspond to the **beginning of the greenup (SOS)** (before maximum value of the VI) and the **end of brown-down (EOS or dormancy)** (after maximum value of the VI). The local minimums of the second derivative curve correspond to the **end of greenup (maturity)** (before maximum value of the VI) and the **beginning of the brown-down (onset of senescence)** (after maximum value of the VI).
- The local maximums of the **THIRD DERIVATIVE** curve before maximum VI value corresponds to the **beginning of greenup (SOS)** and the **end of greenup (maturity)**. The local minimums of the third derivative curve after maximum VI value correspond to the **beginning of the brown-down (onset of senescence)**, and the **end of brown-down (EOS or dormancy)**.

Example of the extraction of phenometrics from a **first (a)**, **second (b)** and **third (c) derivative-based technique**.

Tan, B., et al. (2011). An Enhanced TIMESAT Algorithm for Estimating Vegetation Phenology Metrics From MODIS Data. IEEE Journal of Selected Topics in Applied Earth Observations and Remote Sensing, 4, 361-371

5. PHENOMETRIC EXTRACTION

AUTOREGRESSIVE MOVING AVERAGE TECHNIQUE

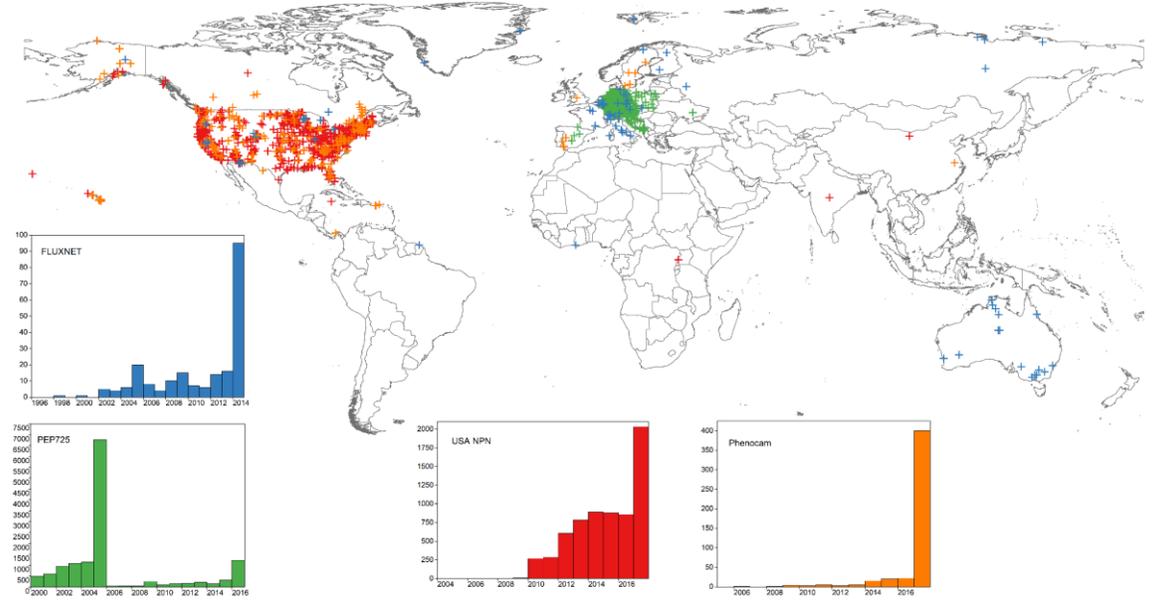

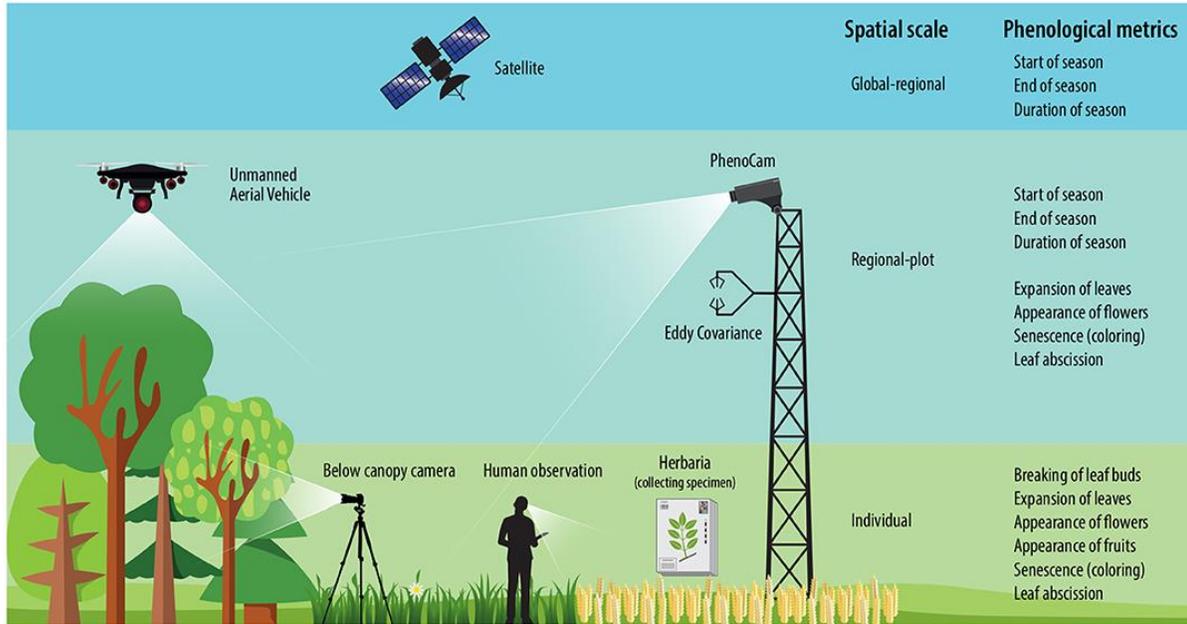

Example of the extraction of phenometrics from **autoregressive moving average technique**.

- **SOS** and **EOS** are determined for each pixel as the intersections of the reference time-series and the forward and backward lagged moving average curves respectively.

Review Article

Land surface phenology as indicator of global terrestrial ecosystem dynamics: A systematic review

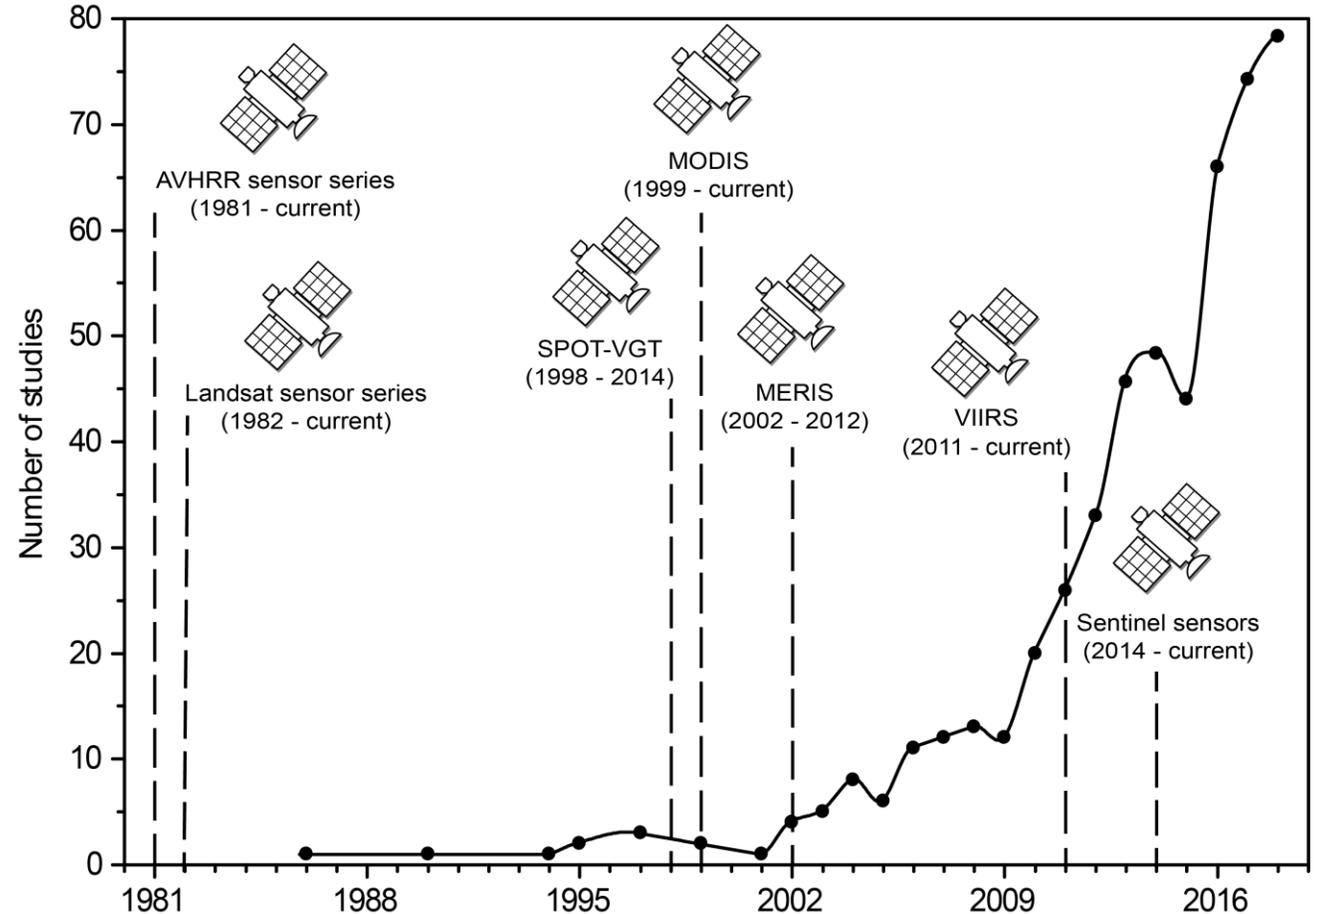

Jose A. Caparros-Santiago^a, Victor Rodriguez-Galiano^{a,*}, Jadunandan Dash^b

^a Departamento de Geografía Física y Análisis Geográfico Regional, Universidad de Sevilla, Sevilla 41004, Spain

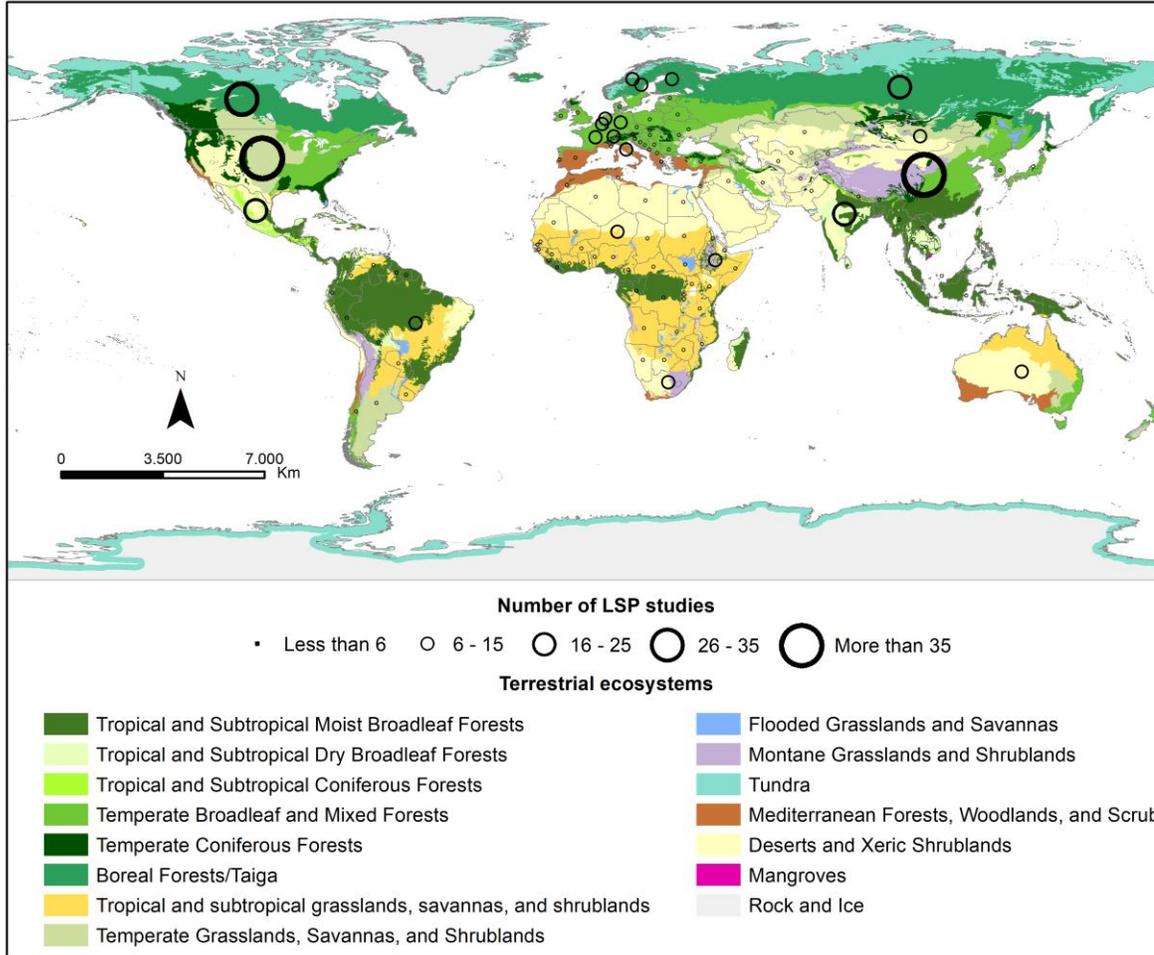

^b School of Geography and Environmental Science, University of Southampton, Southampton SO17 1BJ, United Kingdom

- Before 2000's: 10 studies
- Between 2000-2010: 72
- Between 2010-2019: 435
- Reasons for this:
 - 40 years of data from AVHRR
 - 20 years of data from MODIS
 - Improved temporal resolution of Sentinel-2 (5 days)

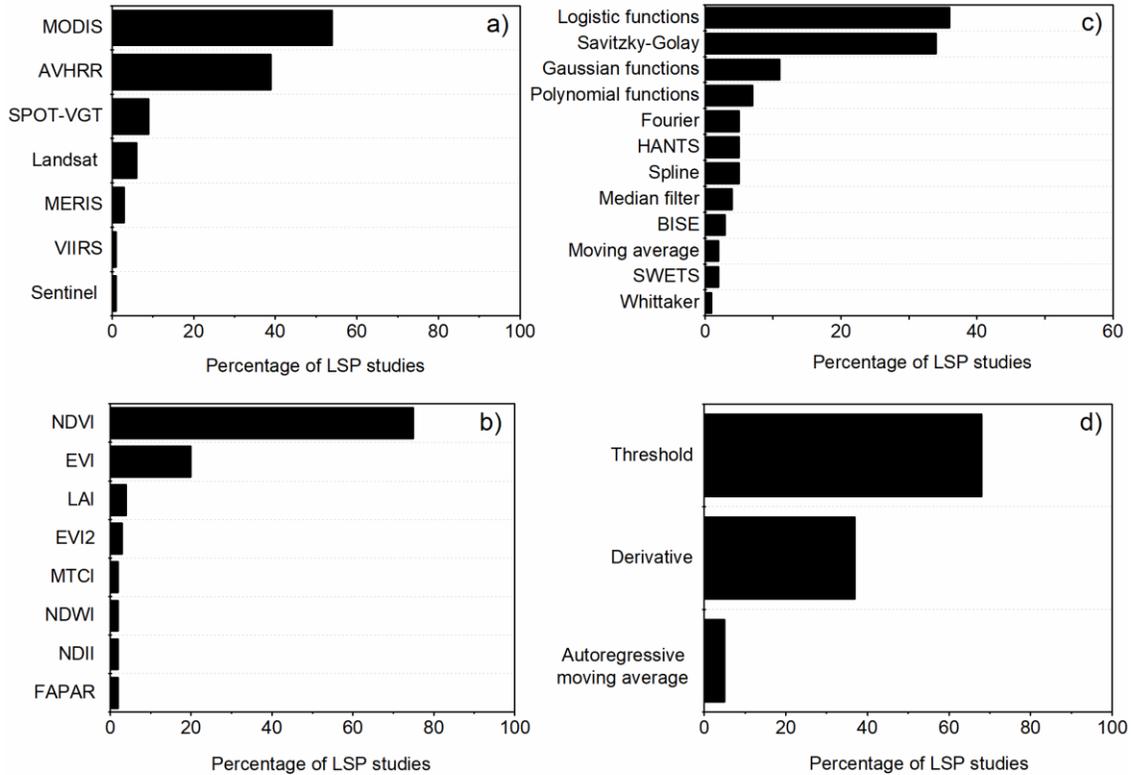

Number of LSP studies from 1980 onwards and timeline of the primary satellite sensors used by said studies. Only sensors used in more than 5 publications are represented.

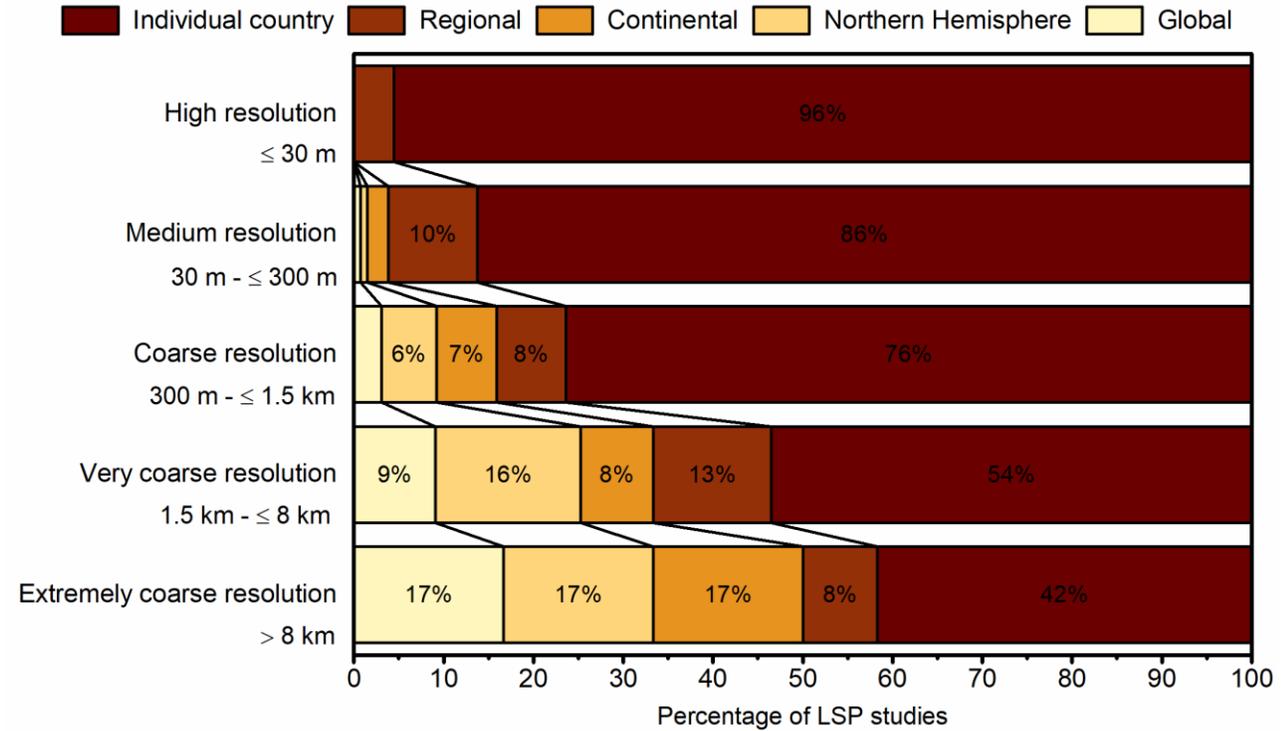

Spatial distribution of LSP studies. This map is based on the ecosystem classification proposed by Olson et al. (2001).

- Boreal and temperate ecosystems are well documented
- Some mid latitude ecosystems highly susceptible to the effect of climate (increasing heat waves and droughts) change are not studied in great detail such as the Mediterranean ecosystems.
- Knowledge of LSP dynamics in a significant portion of tropical ecosystems also remains limited (tropical rainforest: Central and South America, Central Africa or Southeast Asia).
- Tropical or subtropical dry forests, savannas and croplands were the most-studied tropical ecosystems due to their better-defined vegetation seasonality.

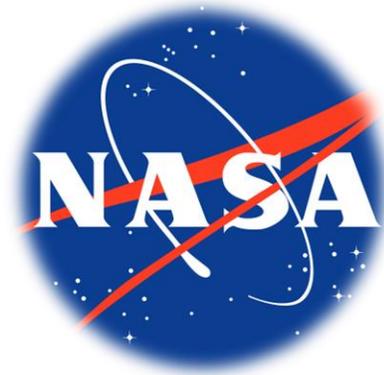

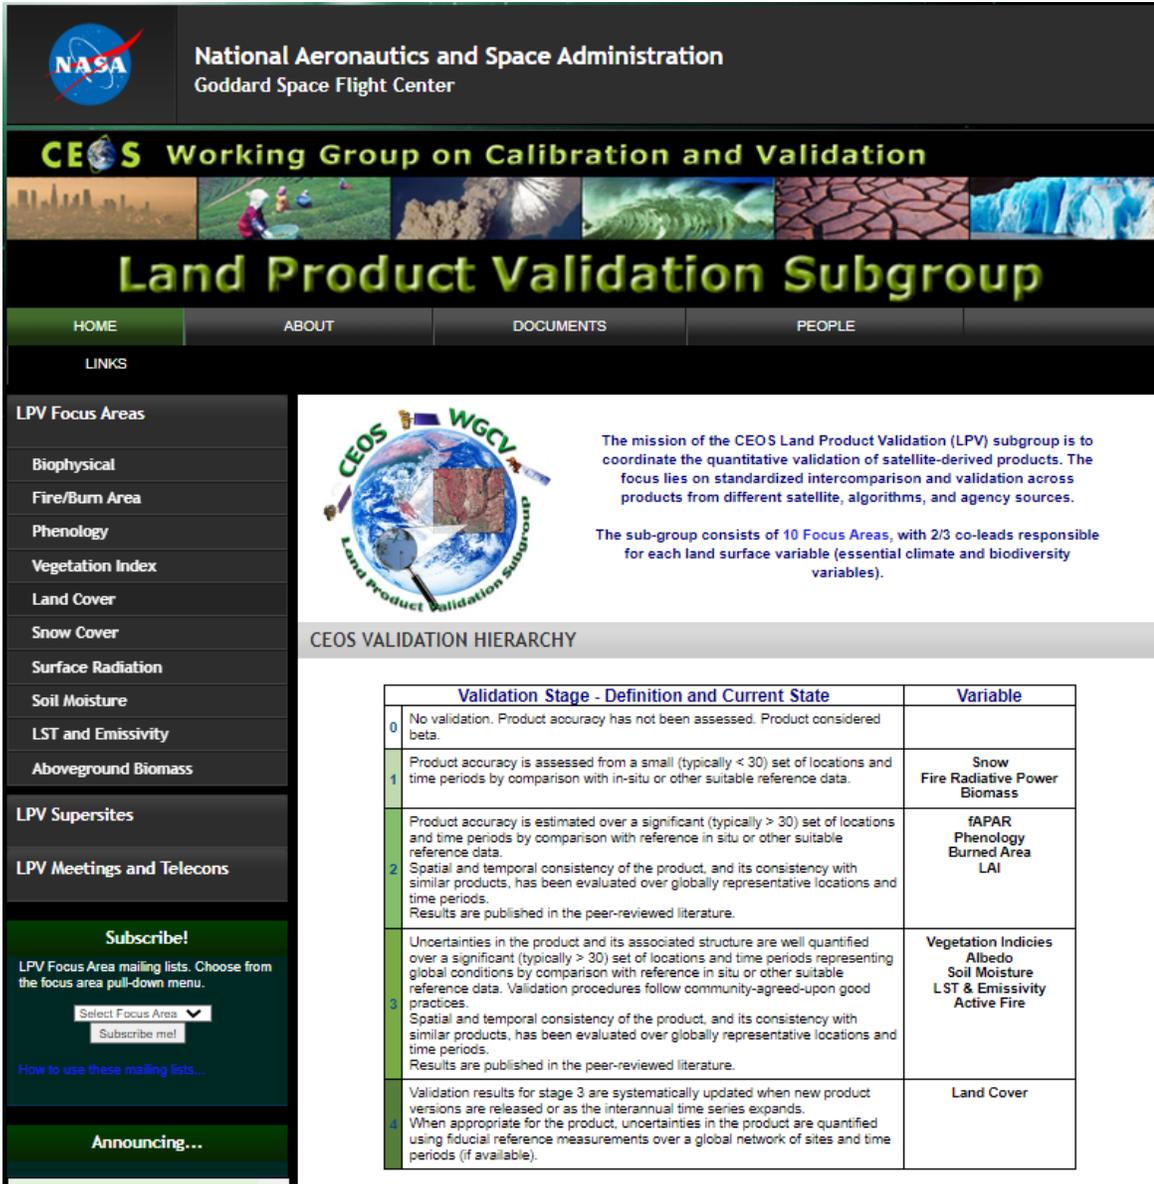

Percentage of LSP studies using: a) sensors; b) VI or biophysical variables; c) smoothing techniques; d) phenometric extraction methods..

Relationship between spatial resolution and the geographic coverage of study areas for different LSP studies..

CEOS Validation Hierarchy

The mission of the CEOS Land Product Validation (LPV) subgroup is to coordinate the quantitative validation of satellite-derived products. The focus lies on standardized intercomparison and validation across products from different satellite, algorithms, and agency sources.

The sub-group consists of 10 Focus Areas, with 2/3 co-leads responsible for each land surface variable (essential climate and biodiversity variables).

Validation Stage - Definition and Current State	Variable
0 No validation. Product accuracy has not been assessed. Product considered beta.	
1 Product accuracy is assessed from a small (typically < 30) set of locations and time periods by comparison with in-situ or other suitable reference data.	Snow Fire Radiative Power Biomass
2 Product accuracy is estimated over a significant (typically > 30) set of locations and time periods by comparison with reference in situ or other suitable reference data. Spatial and temporal consistency of the product, and its consistency with similar products, has been evaluated over globally representative locations and time periods. Results are published in the peer-reviewed literature.	fAPAR Phenology Burned Area LAI
3 Uncertainties in the product and its associated structure are well quantified over a significant (typically > 30) set of locations and time periods representing global conditions by comparison with reference in situ or other suitable reference data. Validation procedures follow community-agreed-upon good practices. Spatial and temporal consistency of the product, and its consistency with similar products, has been evaluated over globally representative locations and time periods. Results are published in the peer-reviewed literature.	Vegetation Indices Albedo Soil Moisture LST & Emissivity Active Fire
4 Validation results for stage 3 are systematically updated when new product versions are released or as the interannual time series expands. When appropriate for the product, uncertainties in the product are quantified using fiducial reference measurements over a global network of sites and time periods (if available).	Land Cover

- The mission of LPV is to coordinate the quantitative validation of satellite-derived products.
- The focus lies on standardized intercomparison and validation across products from different satellite, algorithms, and agency sources.
- The sub-group consists of 10 Focus Areas, with 2/3 co-leads responsible for each land surface variable (essential climate and biodiversity variables).
- The objectives of the Phenology LPV area are:
 - 1. To foster and coordinate quantitative validation of higher level (> Level 2) global land products derived from remotely sensed data.
 - 2. To increase the quality and efficiency of global satellite product validation by developing and promoting international standards and **protocols** for: field sampling, scaling techniques, accuracy reporting, and data and information exchange
